Modafinil and Cognitive Function in Postural Tachycardia Syndrome (POTS)

A common symptom among patients with POTS is “brain fog” or a difficulty in concentrating. We are seeking patients with POTS between 18 and 60 years of age to participate in a research study to better understand this difficulty in concentrating. The purpose of this study is to learn if two drugs, given alone or in combination, can help POTS patients to concentrate.

This study will involve a 6-day stay in the Vanderbilt Clinical Research Center. We will examine how well your autonomic nervous system is working and then give you drugs to see if they help you to concentrate. After receiving each drug we will measure your brain function using tests on a computer, give you some surveys, and measure your blood pressure and heart rate. There is no compensation for this study.

If interested, please reply to:
